Interventional devices in the treatment

of occlusive disease of the lower extremity arteries, including peripheral arterial disease and coronary and carotid artery disease, include several devices that are intended to be delivered via a catheter to a location in the vascular system by conventional catheter delivery systems. Once these devices are in place, including for example stent placement, they are delivered from the catheter on the catheter delivery system. Vascular interventional devices include stent delivery systems that deploy self-

expanding stents of various types, such as balloon expandable stents, self-expanding stents, and stents manufactured from materials that are resilient, such as nitinol. Many of these devices are particularly susceptible to compaction, in the course of deployment, such that they do not expand sufficiently in the vessel to maintain an open lumen. In particular, where they include stents that are manufactured from materials such as nitinol, the materials are especially

susceptible to compaction as they are delivered to the intended treatment location. Many different improvements to stent delivery systems have been made, including adaptations for crimping the stent to the balloon and ensuring a uniform and precise release of the stent from the balloon to allow uniform deployment. Thus, the prior art teaches the use of a specialized balloon and a specialized stent that is crimped onto the balloon, 82138339de
