V.02 -> MIELE 3D | Miele - deutschsprachige 3D SoftwareseiteQ: Markov chain with coin flips, 1 success, rest failures. So I'm trying to understand what the next state is for a Markov chain, where each transition is independent, for a simple 2×2 matrix P . I believe this is relatively straightforward. $A = \begin{matrix} 0.2 & 0.8 \\ 0.8 & 0.2 \end{matrix}$ Let $B = A + I$. Then, $B = \begin{matrix} 0.8 & 1 \\ 1 & 0.8 \end{matrix}$ But I'm having trouble finding P_2 . In particular, I know that P_2 is not a function of P_{11} and P_{12} . So for instance, $P_{11} = 0$ is in a 1 state. But $P_{11} = 0$ does not make it impossible for B to make it to a 2 state. What is P_{12} in this case? My other thought was that the only states that are not strictly increasing in the number of flips are 2 and 3, which both need one success. Is that correct? A: It's easy to see that there's just a single equivalence class of 0-1 states. In your case, suppose (p_{11}, p_{12}) is in the equivalence class for some $0 \leq p_{12} \leq 1 - p_{12} \leq 1$. Consider the 2-steps
